

## Developing carbon metrics for blanket bog – towards a market for carbon storage and sequestration by peatlands

Authors: *Mary-Ann Smyth and Richard Birnie*  
 October 2013  
 Presenter: *Emily Taylor*

### Aims

2

### Strategic fit

Developing carbon metrics for peatland restoration:

- Encourages reduction of UK carbon emissions from land use
- Helps find new ways to fund ecosystem restoration
- Is designed to be parallel with international schemes (eg Verified Carbon Standard), like Woodland Carbon Code (but ETS is not yet open to GHGs from land-use)... so in the mean time is
- Structured for use with the UK's draft pilot Peatland Carbon Code

### Step 1: Development Criteria

- Scientifically credible
- Robust (cope with uncertainties)
- Practical (i.e. can be operated by competent trained individuals)
- Repeatable and suitable for monitoring (clear protocol)
- **Built around an understanding of ecosystem processes**

### Carbon Cycling

5

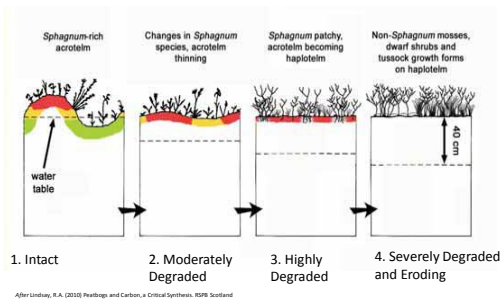

### Background to Approach

- Develop from continental European approach: MoorFutures (Couwenberg et al. 2011)
- Established relationships between peatland vegetation types and measured GHG fluxes
- Identify Greenhouse gas Emission Site Types (GESTs) and derive standard values for GHG fluxes
- Using these standard values to calculate GHG emission savings for proposed restoration projects
- Existing GESTs do not include blanket bogs, the most common type found in the UK

**NEED: TO EXTEND GESTs APPROACH TO INCLUDE BLANKET BOGS**

## Defining Blanket Bog Ecosystem States in relation to peat-forming function

## Step 3: Linking Ecosystem States and Carbon Fluxes

- 13 UK data sets from 6 studies
- 9 data sets from 2 studies on the same Irish blanket bog
- 29 data sets from 6 continental studies (Finland, France, Sweden)
- 51 data sets in total.

Study	Location	Year	State	Flux (gC/m <sup>2</sup> /yr)	SD
1	UK	2008	Intact	20	10
2	UK	2008	Moderately Degraded	-50	15
3	UK	2008	Highly Degraded	-100	20
4	UK	2008	Severely Degraded	-150	25
5	UK	2008	Severely Degraded	-180	30
6	UK	2008	Severely Degraded	-200	35

## Ecosystem States & Carbon Fluxes

### Linking Ecosystem States and Carbon Fluxes

## Ecosystem States & Carbon Fluxes

Peatland Ecosystem State	Description	Carbon flux (gC/m <sup>2</sup> /yr)	
		Mean	Standard Deviation (SD)
1 Fully functional	Peat-forming Sphagnum mosses	-83.4	62.7
2 Moderately Degraded	Grasses, sedges & rushes and some Sphagnum mosses	-33.7	55.0
3 Highly Degraded	Dwarf shrubs and non Sphagnum bryophytes	-18.6	46.0
4 Severely Degraded & Eroded	Bare peat	+23.8	2.4

## Standard values for blanket bogs

BLANKET BOG ECOSYSTEM STATE	Plant Functional Types	Main carbon flux pathways	Mean standard GHG flux grams carbon dioxide equivalent (gCO <sub>2</sub> e/m <sup>2</sup> /yr)	Mean standard GHG flux – tonnes carbon dioxide equivalent per hectare per year (tCO <sub>2</sub> e/ha/yr)
1. INTACT	Peat-forming Sphagnum mosses	Photosynthesis, Oxidation	-365	SINKS 3.0 tonnes
	Non-shrub species	Photosynthesis, Oxidation	-123	SINKS 1.2 tonnes
2. MODERATELY DEGRADED	Shrub species	Photosynthesis, Methane production	-112 (uncertain)	SINKS 1.1 tonnes (uncertain)
3. HIGHLY DEGRADED	Dwarf shrubs	Photosynthesis, Oxidation	-49	SINKS 0.7 tonnes
4. SEVERELY DEGRADED & ERODED	Bare peat	Oxidation and physical erosion	+3129	EMITS 31.0 tonnes
5. ARTIFICIALLY DRAINED	Presence of artificial drainage channels typically @15-20m apart	Photosynthesis, Oxidation physical erosion	+285	EMITS 2.8 tonnes

These estimates of standard values for greenhouse gas balances are based on a limited number of direct observations, over a limited number of sites, and attempt to describe highly variable processes, so they are a **first approximation and should not be considered as absolute values**. However, we believe that these estimates are accurate in terms of their relative orders of magnitude.

## The metrics

- Derived first approximations for standard values for UK blanket bogs. These metrics can be the basis of a carbon calculator for blanket bog restoration.
- Similar to GEST approach in using vegetation as proxy
- BUT set within ecosystem state & transition framework
- Bare peat appears key to driving emissions from drained and eroding blanket bogs. Orders of magnitude effects

## Using these figures

- We used these standard values to estimate the annual greenhouse gas balances associated with blanket bogs in the South Pennines.
- The results show that the **bare peat** surfaces, which occupy less than ten percent of the total peatland area in this region, are **emitting** as much carbon as the other ninety percent of the vegetated peatland area is capturing and storing.

13

## Block grips...

... or reduce grazing

14

## Challenges:

- Work in progress
- Values based on very few direct emissions measurements with considerable uncertainties
- Need more data on magnitude of fluxes through all pathways especially POC and DOC
- Assumption of reversibility of ecosystem transitions
- Need standardised field protocols for operation

## Conclusions...

*Can we use proxies and develop evidence based carbon metrics that would underpin a voluntary code for peatlands?*

- **YES**, it is possible to use proxies, and to develop evidence-based metrics, and we have produced a first approximation.
- We summarised the data required, and designed the approach so that it is standardised and is transferable to other sites.
- Our approach, because it focuses on vegetation and ecosystem functionality, can be used to quantify changes in service provision from specific interventions.

16

## Thank You

## Peat condition & climate

Peatland condition	Type of ecosystem service	Quality of ecosystem service	Flow of ecosystem service	Effect on climate
Healthy peatland	Carbon sequestration and storage	Very good	Improving	Beneficial
Grazed peatland	Carbon storage	Adequate	Steady or deteriorating	Variable
Burnt peatland	Carbon storage	Adequate	Steady or deteriorating	Variable
Degraded peatland	Carbon storage	Poor	Deteriorating	Damaging
Eroding peatland	Carbon storage	Very poor	Deteriorating	Damaging
